

A

What one tie records

supervision.csv holds one row per tie, for a single level

supervision.csv — one row per tie

advisor / advisee	the two people, resolved to author_id where known
relation_type	phd 62 — the only level modelled
institution	where the training happened, ROR-resolved
year_start / year_end	when
confidence	high 62 — every tie
evidence	the source that establishes the tie
advisor_in_frame	true for 13 of 62 ties

Parking the postdoc layer removed every uncertain tie: all 62 that remain are high-confidence.

B

How much of it we see

the lineage covers doctorates only, by decision

Bar length is proportional to recorded positions, so the three levels are comparable in size as well as in coverage.

PhD advisors come from the spreadsheet’s own column.
Postdoc and visiting supervision was researched — seven ties — then parked on 12 September 2026. The positions stay in career_positions.csv; the ties are not modelled.

the network is a PhD lineage, by decision
